

## **Trabajo Práctico N° 1:** **Modelo de Regresión Lineal.**

### **Ejercicio 1.**

Utilizar la base de datos provista “cornwell.dta”.

(a) A partir de los datos de los siete años, y utilizando los logaritmos de todas las variables, estimar un modelo por POLS que relacione la tasa de crimen con *prbarr*, *prbconv*, *prbpris*, *avgsen* y *polpc* y que incluya un conjunto de dummies de año.

POLS:

|          |            |     |            |               |   |        |
|----------|------------|-----|------------|---------------|---|--------|
| Source   | SS         | df  | MS         | Number of obs | = | 630    |
| Model    | 117.644669 | 11  | 10.6949699 | F(11, 618)    | = | 74.49  |
| Residual | 88.735673  | 618 | .143585231 | Prob > F      | = | 0.0000 |
|          |            |     |            | R-squared     | = | 0.5700 |

(c) Implementar un contraste de Correlación Serial.

Stata.

Se rechaza la hipótesis nula de no correlación serial.

(d) Implementar un contraste de Heterocedasticidad.

Stata.

Se rechaza la hipótesis nula de homocedasticidad.

(e) Asumir que se cumple el supuesto de exogeneidad estricta y que  $u_{it}$  sigue un proceso AR(1). Computar el estimador de FGLS siguiendo el enfoque de Prais-Winsten. Una descripción del procedimiento se puede encontrar en Wooldridge (2010), sección 7.8.6. Observación: GLS necesita exogeneidad estricta para conseguir estimadores consistentes.

FGLS:

|          |            |     |            |               |   |         |

(f) *Computar los errores estándar robustos a heteroscedasticidad arbitraria y a autocorrelación serial arbitraria para el modelo con las variables transformadas del inciso previo. Sugerencia de Wooldridge: “... If we have any doubts about the homoskedasticity assumption, or whether the AR(1) assumption sufficiently captures the serial dependence, we can just apply the usual fully robust variance matrix and associated statistics to pooled OLS on the transformed variables. This allows us to probably obtain an estimator more efficient than POLS (on the original data) but also guards against the rather simple structure we imposed on  $\Omega$ . Of course, failure of strict exogeneity generally causes the Prais-Winsten estimator of  $\beta$  to be inconsistent.”*

FGLS (con errores estándar robustos):

|                   |               |   |        |

## Ejercicio 2.

En este ejercicio, se examinará un modelo para el costo total de producción en la industria aeronáutica a modo de ilustrar una aplicación de un modelo heterocedástico por grupos. Considerar la siguiente función de costos:

$$\ln cost_{jt} = \beta_1 + \beta_2 \ln output_{jt} + \beta_3 load\ factor_{jt} + \beta_4 \ln fuel\ price_{jt} + \delta_2 Firm_2 + \delta_3 Firm_3 + \delta_4 Firm_4 + \delta_5 Firm_5 + \delta_6 Firm_6 + \varepsilon_{jt}.$$

(a) Utilizar la base de datos provista “greene97.dta”, la cual contiene datos para seis compañías áreas observadas, anualmente, durante 15 años. Estimar la ecuación por POLS.

|          |            |    |            |               |   |         |

(b) Ahora, asumir que, dentro de cada compañía área, se tiene que:

$$Var[\varepsilon_{jt} | x_{jt}] = \sigma_j^2, t = 1, \dots, T.$$

Por lo tanto, si las varianzas fueran conocidas, el estimador GLS sería:

$$\hat{\beta} = [\sum_{j=1}^N \frac{1}{\sigma_j^2} X_j' X_j]^{-1} \sum_{j=1}^N \frac{1}{\sigma_j^2} X_j' y_j,$$

donde  $X_j$  es una matriz  $T \times K$ . Sin embargo, en este caso práctico, las varianzas son desconocidas. Luego, se solicita computar el estimador de FGLS a través de los siguientes métodos:

(i) Estimar el modelo calculando el estimador necesario para la varianza específica de la compañía áreas a partir de los residuos de OLS, es decir,  $\hat{\sigma}_j^2 = \frac{e_j' e_j}{n_j}$ .

|          |            |    |            |               |   |         |

Wald test of lnsigma2=0: chi2(5) = 1.56

```
Prob > chi2 = 0.9063
```

**(c)** *Comparar los resultados obtenidos en el inciso (b).*

Los resultados obtenidos en el inciso (b) son semejantes en cuanto a valores estimados de los parámetros y a significatividad estadística.

### **Ejercicio 3.**

Considerar la siguiente ecuación de salarios:

$$y_{jt} = \beta_0 + \beta_1 x_{jt} + u_{jt}, j = 1, 2, \dots, N; t = 1, 2 \quad (1)$$

donde  $\beta_0 = \beta_1 = 1$ ,  $u_j \sim \mathcal{N}(0, \Omega)$ ,  $\Omega = \begin{bmatrix} 1 & 0 \\ 0 & 4 \end{bmatrix}$  y  $x_{jt} \sim U[1, 20]$ .

Generar 1.000 muestras de  $N = 5$  observaciones de corte transversal a partir del modelo (1). Para cada muestra, estimar por FGLS los parámetros del modelo y realizar un test de hipótesis para contrastar que  $H_0: \beta_1 = 1$ . Reportar tamaño del test al 1% y el poder del test cuando  $\beta_1 = 0,8$ . Luego, repetir el procedimiento con  $N = 500$ . ¿Se aprecia algún cambio en el tamaño y/o en el poder del test ante el incremento de  $N$ ?

|              | N_5  | N_500 |
|--------------|------|-------|
| tam_test_1   | 2.7  | 1     |
| poder_tes~08 | 33.2 | 100   |

Por lo tanto, se puede observar que, ante el incremento de  $N$ , el tamaño del test tiende al nivel de significación del 1% y el poder del test tiende al 100%.
